The present invention relates generally to semiconductor device manufacturing, and more particularly, to a method of improving leakage current reduction in semiconductor memory devices. In the field of semiconductor device fabrication, a gate structure is one of the basic building blocks. It can be used to form a transistor which is incorporated into the operation of a semiconductor device. In particular, a gate structure is a critical structure in the fabrication of a metal oxide semiconductor (MOS) transistor. In a

conventional gate structure, the gate stack is constructed out of layers of materials that include a metal gate electrode, a dielectric material and a hardmask material. Each of these layers are formed on a semiconductor substrate using conventional semiconductor fabrication methods, and they are patterned in order to form a gate electrode for the MOS transistor. The dielectric material layer is usually formed using an oxide, and the hardmask material is usually silicon nitride. During semiconductor device manufacture, the quality and thickness of the gate structure is important for the performance of the resulting device. As integrated circuits become more highly integrated with the distance between features becoming smaller and smaller, it becomes more difficult to maintain the characteristics and
